Overview

Capacitor is one of the passive component (cannot generate energy on their own) in Electronics. This Capacitor is capable of storing electric charge in it and and this results in developing a voltage or in other wor. The construction of Capacitor is quite simple. It consists of a two conductive plates like the ones shown in the above diagram (Plate 1 and Plate 2) where these two plates are se. Let's consider DC first and see how it reacts to DC. Initially the Capacitor will be in discharged. As stated earlier Capacitor reacts differently when supplied with AC voltage. When DC voltage is applied Capacitor charges only in one direction. However when AC is applied Capacitor charge. Another key thing to know about Capacitors in AC circuits is that they offers resistance to the Current flow in AC circuits. This is referred to Reactance and more specifically Capacitive React.

Electrolytic capacitor

An electrolytic capacitor is a polarized capacitor whose anode or positive plate is made of a metal that forms an insulating oxide layer through anodization. This oxide layer acts as the dielectric of the capacitor. A solid, liquid, or gel electrolyte covers the surface of this oxide layer, serving as the cathode or negative plate of the capacitor. Because of their very thin dielectric oxide ...
